

Homework 9

**\*\* Problem 1.** For a Hilbert space  $V$ , show that the norm defined by  $\|v\| = (v|v)^{1/2}$  is an actual norm.

*Proof.* We already know  $(v|v) \geq 0$  and  $(v|v) = 0$  if and only if  $v = 0$ . Thus,  $\|v\| = (v|v)^{1/2} \geq 0$  and  $\|v\| = 0$  means  $(v|v) = 0$  and so  $v = 0$ . Now consider  $\alpha \in \mathbb{C}$ . We have

$$\|\alpha v\| = (\alpha v|\alpha v)^{\frac{1}{2}} = (\alpha(v|\alpha v))^{\frac{1}{2}} = (\alpha\bar{\alpha}(v|v))^{\frac{1}{2}} = |\alpha|(v|v)^{\frac{1}{2}} = |\alpha|\|v\|.$$

Finally, for  $w \in V$ , we have

$$\|v + w\|^2 = (v + w|v + w) = \|v\|^2 + \|w\|^2 + (v|w) + (w|v) = \|v\|^2 + \|w\|^2 + 2\operatorname{Re}(v|w).$$

The triangle inequality follows using Cauchy-Schwartz. □

**\*\* Problem 2.** Show  $\widehat{(\mathbb{R}, +)} = \{\chi_t \mid t \in \mathbb{R}, \chi_t(x) = e^{itx}\}$ .

*Proof.* Given  $\chi \in \widehat{(\mathbb{R}, +)}$  we want to show there exists  $t \in \mathbb{R}$  such that  $\chi = \chi_t$ . Let  $H$  be the kernel of  $\chi$  and note that  $H$  is a closed subgroup of  $\mathbb{R}$  under addition. Either  $H = \mathbb{R}$ ,  $H = \{0\}$  or there exists  $b \in \mathbb{R}^+$  such that  $H = \{nb \mid n \in \mathbb{Z}\}$ . In the case  $H = \mathbb{R}$  we know  $\chi = 1$  and  $t = 0$  suffices. The case  $H = \{0\}$  is impossible since  $\chi(0) = \chi(2n\pi)$ . Consider the third case. Note  $\chi(b/2)^2 = \chi(b) = 1$  and since  $b/2 < b$ ,  $\chi(b/2) = -1$ . Now note  $\chi(b/4)^2 = \chi(b/2) = -1$  and so  $\chi(b/4) = \pm i$  and without loss of generality we can choose  $\chi(b/4) = i$ . We show by induction on  $n$  that for  $n \geq 2$ ,  $\chi(b/2^n) = e^{i\pi/2^{n-1}}$ . We have shown this for the base case,  $n = 2$ , so now assume that for some  $n \geq 2$  the result holds. Consider  $\chi(b/2^{n+1})$ . Note that  $\chi(b/2^{n+1})^2 = \chi(b/2^n) = e^{i\pi/2^{n-1}}$ . Then we have  $\chi(b/2^{n+1}) = \pm e^{i\pi/2^n}$ . Note that  $\chi((-b/4, b/4))$  must map to  $\{e^{i\theta} \mid -\pi/2 < \theta < \pi/2\}$  from continuity. Therefore  $\chi(b/2^{n+1}) = e^{i\pi/2^n}$ . Now consider  $x \in [0, b]$  and create a sequence  $a_m$  such that  $a_m$  converges to  $x$  and  $c_m = kb/2^n$  for some  $k \in \mathbb{R}$ . Then  $\chi(c_m) = \chi(b/2^n)^k = e^{ik\pi/2^{n-1}}$  and since  $\chi$  is continuous this must converge to  $\chi(x) = e^{2\pi ix/b}$ . Therefore  $t = 2/b$ . □

**\*\* Problem 3.** Show  $\widehat{\mathbb{T}} = \{\chi_n \mid n \in \mathbb{Z}, \chi_n(e^{i\theta}) = e^{in\theta}\}$ .

*Proof.* Note that  $\mathbb{T}$  is the quotient of  $(\mathbb{R}, +)$  by the subgroup  $[0, 2\pi)$ . We can thus use the proof in \*\* Problem 2 where  $b = 2\pi$ . □
